

Ohdo Syndrome, Say-Barber-Biesecker-Young-Simpson Variant

Subjects: Genetics & Heredity

Contributor: Rita Xu

The Say-Barber-Biesecker-Young-Simpson (SBBYS) variant of Ohdo syndrome is a rare condition characterized by genital abnormalities in males, missing or underdeveloped kneecaps (patellae), intellectual disability, distinctive facial features, and abnormalities affecting other parts of the body.

Keywords: genetic conditions

1. Introduction

Males with the SBBYS variant of Ohdo syndrome typically have undescended testes (cryptorchidism). Females with this condition have normal genitalia.

Missing or underdeveloped patellae is the most common skeletal abnormality associated with the SBBYS variant of Ohdo syndrome. Affected individuals also have joint stiffness involving the hips, knees, and ankles that can impair movement. Although joints in the lower body are stiff, joints in the arms and upper body may be unusually loose (lax). Many people with this condition have long thumbs and first (big) toes.

The SBBYS variant of Ohdo syndrome is also associated with delayed development and intellectual disability, which are often severe. Many affected infants have weak muscle tone (hypotonia) that leads to breathing and feeding difficulties.

The SBBYS variant of Ohdo syndrome is characterized by a mask-like, non-expressive face. Additionally, affected individuals may have distinctive facial features such as prominent cheeks, a broad nasal bridge or a nose with a rounded tip, a narrowing of the eye opening (blepharophimosis), droopy eyelids (ptosis), and abnormalities of the tear (lacrimal) glands. About one-third of affected individuals are born with an opening in the roof of the mouth called a cleft palate. The SBBYS variant of Ohdo syndrome can also be associated with heart defects and dental problems.

2. Frequency

The SBBYS variant of Ohdo syndrome is estimated to occur in fewer than 1 per million people. At least 19 cases have been reported in the medical literature.

3. Causes

The SBBYS variant of Ohdo syndrome is caused by mutations in the *KAT6B* gene. This gene provides instructions for making a type of enzyme called a histone acetyltransferase. These enzymes modify histones, which are structural proteins that attach (bind) to DNA and give chromosomes their shape. By adding a small molecule called an acetyl group to histones, histone acetyltransferases control the activity of certain genes. Little is known about the function of the histone acetyltransferase produced from the *KAT6B* gene. It appears to regulate genes that are important for early development, including development of the skeleton and nervous system.

The mutations that cause the SBBYS variant of Ohdo syndrome likely prevent the production of functional histone acetyltransferase from one copy of the *KAT6B* gene in each cell. Studies suggest that the resulting shortage of this enzyme impairs the regulation of various genes during early development. However, it is unclear how these changes lead to the specific features of the condition.

3.1. The Gene Associated with Ohdo Syndrome, Say-Barber-Biesecker-Young-Simpson Variant

- *KAT6B*
-

4. Inheritance

This condition has an autosomal dominant inheritance pattern, which means one copy of the altered gene in each cell is sufficient to cause the disorder. Almost all reported cases have resulted from new mutations in the gene and have occurred in people with no history of the disorder in their family.

5. Other Names for This Condition

- blepharophimosis and mental retardation syndrome, Say-Barber/Biesecker/Young-Simpson type
- blepharophimosis-intellectual deficit syndrome, Say-Barber/Biesecker/Young-Simpson type
- BMRS SBBYS
- Ohdo syndrome, Say-Barber-Biesecker variant
- Ohdo syndrome, SBBYS variant
- Say-Barber-Biesecker-Young-Simpson syndrome
- Say-Barber-Biesecker-Young-Simpson variant of Ohdo syndrome
- SBBYS variant of Ohdo syndrome
- SBBYSS
- Young-Simpson syndrome
