

# Abiotic Stress in Plants

Subjects: **Plant Sciences**

Contributor: . Harish

Abiotic stress in plants is a crucial issue worldwide, especially heavy-metal contaminants, salinity, and drought. These stresses may raise a lot of issues such as the generation of reactive oxygen species, membrane damage, loss of photosynthetic efficiency, etc. that could alter crop growth and developments by affecting biochemical, physiological, and molecular processes, causing a significant loss in productivity. To overcome the impact of these abiotic stressors, many strategies could be considered to support plant growth including the use of nanoparticles (NPs). However, the majority of studies have focused on understanding the toxicity of NPs on aquatic flora and fauna, and relatively less attention has been paid to the topic of the beneficial role of NPs in plants stress response, growth, and development. More scientific attention is required to understand the behavior of NPs on crops under these stress conditions.

## 1. Introduction

In the current scenario, population explosion has emerged as one of the major challenges, especially for sustainable food production, in feeding the growing population <sup>[1]</sup>. The world population may reach up to 10.9 billion by 2100 and will lead to an increase in demand for food by nearly 50%. To achieve the “Zero Hunger” goal, which is one of the goals of sustainable development of the UN to be achieved by 2030, there is an urgent need for revolutionizing conventional agricultural practices. Such changes can be achieved by employing eco-friendly and sustainable innovations <sup>[1][2][3][4]</sup>.

Plants are unable to move physically from their location to prevent the consequences of environmental stress such as abiotic stresses. Among different abiotic stresses, heavy metal (HM) contamination, soil salinity, and drought stress are described to limit the crop productivity by multiple orders of magnitude <sup>[5][6][7]</sup>. These changes under abiotic stress trigger perturbations in the metabolism of plants, thereby facilitating reorganization of the metabolic network in order to keep the vital metabolic processes active <sup>[8][9][10][11][12]</sup>.

Soil pollutants, especially HMs and metalloids such as Cr, Cd, Ni, Zn, As, and Hg, are identified as the most commonly detected contaminants <sup>[13][14]</sup>. The increased release of HMs in the terrestrial environment has been documented to severely affect the productivity of cultivated areas <sup>[15][16]</sup>. Furthermore, most of the metal contaminants eventually find their way into the terrestrial and aquatic environment, thereby directly or indirectly affecting human health and the associated ecosystems <sup>[17][18]</sup>. Additionally, there are ample chances of accumulation of HMs in plants exposed to contaminated areas <sup>[19]</sup>.

Salinity and drought stresses are devastating stresses that are reported to limit the economic yield of several crops via inducing biochemical and physiological perturbations [20][21][22]. These stresses confine the plant productivity and growth due to osmotic stress, nutritional imbalance, and oxidative stress [23]. The salt stress results in the accumulation of sodium ( $\text{Na}^+$ ) and chloride ( $\text{Cl}^-$ ) ions in the cytosol, eventually causing considerable damage to the cell [24]. Drought stress is known to induce stomatal closure, to inhibit photosynthesis, to reduce the leaf area, to reduce the biomass and growth, to decrease the water potential, to increase the amount of osmolytes, and to induce the generation of reactive oxygen species (ROS) [25]. Abiotic stress triggers perturbation in the metabolism of plants, thereby facilitating reorganization of the metabolic networks in order to keep the vital processes active [8][9][10][11][12]. Thus, the onset of abiotic environmental stressors because of immobile nature of plants eventually leads to reduced crop productivity.

Numerous stress management strategies have been developed by researchers in recent decades. Among them, nanotechnology is one of the emerging strategies that has been anticipated to improve crop productivity [2][3]. Nevertheless, most of the research focusing on nanoparticles (NPs) currently is concentrated on their toxicity [4][26][27][28][29]. Relatively fewer publications are available regarding the role of NPs in crop protection, especially under various abiotic stress conditions [8][30][31].

Nanoparticles may be described as materials with diameters between 1 to 100 nm in at least one dimension [32]. Metal and metal-based NPs show various physiochemical features that are different from their native bulk compounds. The application of NPs has gained widespread popularity in agriculture and allied sectors including various other fields, i.e., the chemical, optical, biomedical, pharmaceutical, food, and textile industries [33][34]. Different NPs for field applications such as nano-agrochemicals have been used to increase agricultural productivity. Some of them include phosphorous NPs ( $\text{Ca}_5(\text{PO}_4)_3\text{OH}$ ), calcium NPs ( $\text{CaCO}_3$ ), Mg NPs, ZnO NPs,  $\text{Fe}_2\text{O}_3$  NPs,  $\text{TiO}_2$  NPs, Ag NPs ( $\text{AgNO}_3$ ), Mn NPs ( $\text{MnSO}_4$ ), Cu NPs ( $\text{CuO}$ ), Mo NPs,  $\text{SiO}_4$  and  $\text{AlO}_4$  CNTs (carbon nanotubes), and a complex of Chitosan with Zn or Cu [4][35].

Nanoparticles as soil-improving agents, nano-fertilizers, nano-pesticides, growth stimulators, and nano-sensors for controlling various agricultural factors in the farm [36] have been utilized for improving crop yield. It has gained popular acceptance for its potential application in the smart and controlled delivery of pesticides and herbicides and in the sustained-release of fertilizer formulations. Additionally, the contribution of NPs in the alleviation of abiotic stress-induced toxicity in plants is of immense agricultural importance. The intervention of nanotechnology has demonstrated effectiveness not only in the removal of non-degradable metals, but also in the detoxification of slowly degrading contaminants [37]. The past decades have substantially received tremendous contribution about NPs improving plant growth and soil characteristics, particularly in the management of marginal soils affected by HM contamination [38][39]. In a recent study, the contents of chlorophyll (a and b) and carotenoids were noticeably enhanced by magnetic NP treatment to *Hordeum vulgare*, apart from the positive impacts on the genes of photosystems [40]. Likewise, the negative impacts of drought and salinity stress have also been mitigated by the use of NPs [41][42].

In order to obtain in-depth knowledge on field applications of NPs, the present review aimed to discuss the challenges of different abiotic stresses causing substantial changes in crops at the morphological, anatomical, biochemical, and physiological levels and the possible roles and mechanisms of NPs for mitigating the negative consequences of abiotic stresses to improve the agricultural productivity.

## 2. Alleviation of Heavy Metal Toxicity in Plants Using Nanoparticles

Excessive release of HMs in the environment by an exponential rise in anthropogenic activities and industrial processing is of great concern [43][44]. The risks of HM contamination in cultivated fields and aquatic environments due to the indiscriminate addition of various agro-fertilizers are of considerable concern [45][46]. The abundance of HMs in a given environmental matrix beyond certain limits exerts toxicity because of accumulation and genotoxic, carcinogenic, and mutagenic behaviors [46][47][48][49].

The HMs and metalloids associated with the environmental and human health concerns include Cu, Zn, Cd, Cr, Pb, As, and Hg [50][51]. Therefore, it is imperative to develop innovative and economical technologies for the successful elimination of HMs from contaminated sites. However, the characteristic toxicity at low concentrations, slow removal using conventional approaches, and non-biodegradable attributes of HMs [49][52][53][54] are the important factors imposing restrictions in successful detoxification from contaminated sites. The fabrication of effective and eco-friendly NPs for successful employment in managing widespread contamination of hazardous HMs has received much popularity [55]. Among the different metal and non-metal-based NPs, generally, those with an environmentally friendly nature, cost-effectiveness, and ease of availability are preferred for application in environmental clean-up programs as well as in the alleviation of toxicity [56].

The contribution of myriads of NPs in overcoming the challenges of HM-induced toxicity has been presented by various researchers worldwide (Table 1). In general, it has been observed that NPs minimize the uptake of HMs by modifying the expression of genes responsible for metal uptake and by reducing HM bioaccumulation. Furthermore, NP treatment improves the physiological and biochemical parameters of the plants such as enhancing the synthesis of defense enzymes (SOD, POX, CAT, APX, etc.); augmenting nutrient uptake; decreasing the loss of electrolytes; improving pigments and soluble proteins; reducing peroxidation; and causing rise in the levels of proline, glutathione, and phyto-chelatins. These attributes are primarily responsible for the overall increase in the tolerance of the crops and may vary slightly according to different plant species.

**Table 1.** Applications of NPs in the mitigation of HMs stress by altering the morphophysiological responses of plants.

Nanoparticles	Plants	Germination and Morphological Responses	Physiological Responses	References
Si (10 µM)	<i>Pisum sativum</i> L.	Presence of Si NPs improved the growth in	Si NPs minimized the Cr storage, enhanced the	[57]

### 3. Alleviation of Salinity Stress in Plant Using Nanoparticles

Salinity is a major abiotic stress affecting crop production worldwide. It is caused by the accumulation of salts in the soil, which leads to osmotic stress and ion toxicity. Salinity stress affects plant growth and development, leading to reduced yields. Nanoparticles have been used to alleviate salinity stress in plants. They can improve plant growth and development, increase the tolerance of plants to salinity stress, and reduce the accumulation of salts in plants. Nanoparticles can also improve the efficiency of nutrient uptake by plants, leading to increased yields. The use of nanoparticles to alleviate salinity stress in plants is a promising area of research.

- of *T. aestivum* L. with Ag NPs was also proven to be an adequate salinity stress management strategy [83].

**Figure 1.** Salinity and drought stress-mediated responses in the plants; ETS: electron transport system.

- Nanoparticles can help the plant under salt stress by regulating ion balance, reducing the Na<sup>+</sup> ion toxicity, increasing the uptake of K<sup>+</sup>, activating the antioxidative defense system, increasing the contents of the pigment, compatible solutes, and increasing stomatal conductance. In salinity-stressed *T. aestivum* L., the application of magnetite NPs improved chlorophyll contents and antioxidative enzymes along with the amelioration of various polypeptide chains which are reported to be linked with salinity stress tolerance [78]. Nano-SiO<sub>2</sub> improved the growth of *G. max* under salt stress by raising the level of leaf K<sup>+</sup> and biological antioxidant activities [79]. Similarly, in salt-stressed *T. aestivum* L. cultivars, nano-SiO<sub>2</sub> was found to improve seed germination and growth [80].
- The application of Zn NPs to salt-stressed *Brassica napus* plants alleviated the salinity-induced detrimental impacts by upregulating the antioxidative mechanism, osmolyte biosynthesis, and ionic control [82]. In *Solanum lycopersicum*, Cu NPs applied to the leaves mitigated salinity stress by improving growth and the Na<sup>+</sup>/K<sup>+</sup> ratio. Moreover, Cu NPs improved the level of glutathione, polyphenols, and vitamin C content as compared to the control. Additionally, the activities of APX, GRX, and SOD were also modulated, thereby improving the overall plant's normal growth and development [82]. In addition, seed priming with ZnO NPs (60 mg/L) ameliorated the detrimental consequence induced by the NaCl treatment in *Lupinus termis* via increasing the pigments, osmoregulation, and regulation of the contents of stress-associated metabolites. In another study, the seed priming of *T. aestivum* L. with Ag NPs was also proven to be an adequate salinity stress management strategy [83].
