Cyberlindnera jadinii is widely used as a source of single-cell protein and is known for its ability to synthesize a great variety of valuable compounds for the food and pharmaceutical industries. Its capacity to produce compounds such as food additives, supplements, and organic acids, among other fine chemicals, has turned it into an attractive microorganism in the biotechnology field.
Ecology, Taxonomy, and Evolution

The natural environment of Cyberlindnera jadinii is still an open question. It is thought that it may be associated with the decomposition of plant material in nature, as it is able to assimilate pentoses and tolerate lignocellulosic by-products [3], displays great fermentative ability, and is copiotrophic [13]. The current laboratory strains were isolated from distinct environments, namely, from the pus of a woman abscess (CBS 1600/NRRL Y-1542), a cow with mastitis (CBS 4885/NRRL Y-6756), a yeast deposit from a distillery (CBS 567), yeast cell factories (CBS 621), and flowers (CBS 2160) [3][6][7][8][12]. The extensive nomenclature revisions of this species are well described in “The tortuous history of Candida utilis” by Barnet [14]. In 1926, this yeast was isolated from several German yeast factories, which had been cultivated without a systematic name during the time of World War I for food and fodder [14]. It was first named Torula utilis being later referred to as Torulopsis utilis (1934). The “food yeast” was also designated as Saccharomyces jadinii (1932), Hansenula jadinii (1951), Candida utilis (1952), Pichia jadinii (1984), and Lindnera jadinii (2008) [12][14][15][16]. From the aforementioned, C. utilis was the nomenclature most commonly used, having almost 1000 published papers in PubMed (results available at: https://pubmed.ncbi.nlm.nih.gov/?term=%22candida+utilis%22; Accessed 16 October 2020). The Candida genus comprised species that form pseudohyphae or true hyphae with blastoconidia, among other standard characteristics [17][18][19]. In the classification system implemented in 1952 by Lodder and Kreger-van Rij, the Candida genus included yeasts that produce only simple pseudohyphae [14]. At that time, the majority of the isolates was renamed as C. utilis [18]. Later, the C. utilis was established as an asexual state of a known ascosporogenous yeast, Hansenula jadinii, as it was found to share some similarities between phenotypic traits [20]. In 1984, even though concurring with a publication of an extensive chapter of the genus Hansenula, Kurtzman moved most of the Hansenula species to the Pichia genus, due to their “deoxyribonucleic acid relatedness.” Thus, C. utilis was renamed Pichia jadinii. A quarter of a century later, this yeast species was again renamed as Lindnera jadinii based on analyses of nucleotide sequence divergence in the genes coding for large and small-subunit rRNAs [12]. Species integrated into the Lindnera differ considerably in ascospore morphology ranging from spherical to hat-shaped or Saturn-shaped spores. In addition, this clade includes both hetero- and homothallic species and physiological features as fermenting glucose and assimilating a variety of sugars, polyols, and other carbon sources are defining characteristics of the Lindnera genus [12]. Finally, 1 year later, the genus Lindnera was replaced by Cyberlindnera, as the later homonym defined a validly published plant genus [15]. This substitution occurred in 21 new species, including Cyberlindnera jadinii [15]. In summary, any of the aforementioned nomenclatures reported in the literature may refer to the same organism since C. utilis is the anamorph state and C. jadinii the teleomorph state [14]. The anamorph represents the asexual stage of a fungus contrasting with the teleomorph form that defines the sexual stage of the same fungus [21]. The primary name of a species relies on the sexual state or teleomorph, but a second valid name may rely on the asexual state or anamorph [22]. However, this should only happen when teleomorphs have not been found for a specific species or it is not clear if a particular teleomorph is the same species as a particular anamorph. Accordingly, since 2013, the International Botanical Congress states that the system for allowing separate names for the anamorph state should end [23]. The new International Code of Nomenclature for algae, fungi, and plants, the Melbourne Code, supports the directive that fungal species or higher taxon should be assigned with a single valid name. Accordingly, anamorph yeast genera like Candida should be revised to turn the genus consistent with phylogenetic affinities [19]. Notwithstanding, the reclassification of several C. utilis as C. jadinii in several culture type collections is still confusing, reaching a point where the same strain is designated as C. utilis and C. jadinii in different culture type collections. This aspect, together with the previous nomenclatures used in research papers, leads to unnecessary misunderstandings. To clarify this, Table 1 presents the alternative designations of the main laboratory strains.

Table 1. Main C. jadinii (former C. utilis) strains described in literature.

a This strain has been discontinued in ATCC. b The strain number reported in the literature is not available in the Culture Collection of Yeasts (CCY), all C. jadinii strains are registered as 029-38-XX, including C. jadinii 029-38-18, the likely match to CCY 39-38-18.

C. jadinii belongs to the phylum Ascomycota, subphylum Saccharomycotina. The members of this subphylum constitute a monophyletic group of ascomycetes that are well defined by ultrastructural and DNA characteristics [13]. These include lower amounts of chitin in overall polysaccharide composition at cell walls, being unable to stain with diazonium blue, low content of guanine and cytosine (G + C < 50%) at nuclear DNA, and presence of continuous holoblastic bud formation with wall layers. C. jadinii belongs to the Saccharomycetes class, Saccharomycetidae family, Saccharomycetales order, and the Cyberlindnera genus. However, a comprehensive phylogenetic analysis and evolutionary relationship are still missing for this species [36][37][38]. Aiming at filling this gap, we performed a robust phylogeny reconstruction [36][39][40][41]. As can be depicted in Figure 1, this yeast localizes in the Phaffomycetaceae clade together with Cyberlindnera fabiani and Wickerhamomyces ciferri. The nearest neighbors belong to the Saccharomycetaceae family, which includes a clade with S. cerevisiae/Torulaspora delbrueckii species and another clade with Eremothecium goessiyii (former Ashbya goessiyii), Kluyveromyces lactis/marxianus, and Lachancea species. Despite the previous genus nomenclature adopted for C. jadinii (Candida and Pichia), it is phylogenetically distant from the Debaryomycesaceae and Pichiaceae families that include the Candida species, except C. glabrata, the Pichia kudriavzevii, and Ogataea species. Komagataella phaffii is as expected included in the Pichiaceae clade, together with Komagataella pastoris [36][40]. The Trichomonascaceae/ Dipodascaceae clade, formerly known as the Yarrowia clade, includes now the Sugiyamaella lignohabitans species together with Yarrowia lipolytica, and is the most distant yeast
clade, except for the Schizosaccharomycetaceae that clusters with all the Basidiomycota. The filamentous fungi Neurospora crassa and Fusarium graminearum are in different clades as members of the Sordariaceae and Nectriaceae clades, respectively. In addition, in the Sordariaceae clade, the phylogenetic position of Thermotheleomyces thermophila species (Myceliophthora thermophila) was uncovered.

**Figure 1.** Evolutionary relationship of Cyberlindnera jadinii, a member of the Phaffomycetaceae clade. The phylogenetic reconstruction was obtained using the following parameters: maximum likelihood in IQ-TREE (http://www.iqtree.org), the model of amino acid evolution JTT (Jones-Taylor-Thornton), and four gamma-distributed rates. Homologues were detected for 1567 proteins across the proteome of 77 selected fungal species from NCBI. The 1567 set of proteins were aligned and then concatenated in order to use in the phylogenetic analysis. These proteins offer a clear high-resolution evolutionary view of the different species, as they are essential proteins beyond the specific biology of the different yeasts. Bootstrapping provided values of 100% for all the nodes. Yeast and fungi families are highlighted with different colors and shades. The phylogenetic relationships reflect evolutionary ancestries, independently of adaptations and overall gene contents within the various species. All families with more than one representative species in the analyses formed monophyletic groups.

**Morphology and Physiology**

The C. jadinii microscopic view provided by Kurtzman et al. (2011) has shown the diversity of cell shapes and sizes after 10–30 days at 25 °C in 5% Malt Extract Agar media. The cell patterns of C. jadinii CBS 1600 varied from ellipsoidal to elongated occurring in single cells or in pairs. Some pseudohyphae forms were also detected with diameter balanced between (2.5–8.0) and (4.1–11.2) µm.

**Figure 2** shows C. jadinii DSM 2361 strain cultivated on YPD or Malt Extract Agar media for 3 (A and C) and 12 days (B and D) at 30 °C. The colonies are white, round, with a smooth texture, an entire margin, and a convex elevation trait. Cells present an ellipsoidal to elongated form, with a diameter between 5 and 7.5 µm. Yeast cell morphology can be tightly influenced by the environment. These modifications can affect the fermentation performance by inducing rheological changes that can influence mass and heat transfer alterations in the bioreactor. However, in a study performed by Pinheiro et al.
(2014), the CBS 621 strain cultured in a pressurized-environment triggered with 12 bar air pressure presented no significant differences in cell size and shape [33]. C. jadinii is a homothallic species and forming hat-shaped ascospores that can be present in a number of one to four in unconjugated deliquescent asci [34]. 

Cyberlindnera species can assimilate several compounds, namely, sugars and organic acids. The robust fermentation characteristics of C. jadinii allow growth in a diversity of substrates from biomass-derived wastes, including hardwood hydrolysates from the pulp industry, being able to assimilate glucose, arabinose, sucrose, raffinose, and D-xylose [8][9][10][44]. As previously mentioned, C. jadinii is a Crabtree-negative yeast, reaching higher cell yields under aerobic conditions [45][46][47] than Crabtree-positive species. The Crabtree-negative effect favors the respiration process over fermentation, enabling the development of phenotypes relevant for protein production [48]. This species has a high tolerance to elevated temperatures, being able to grow in a broad spectrum of temperatures from 19 to 37 °C [37] and to tolerate long-term mild acid pHs (~3.5) [49]. Another relevant property is the ability to release proteins to the extracellular medium [50]. Significant lipase and protease content were achieved using a wild C. jadinii strain isolated from spoiled soybean oil, using solid-state fermentation [51][52]. C. jadinii assimilates alcohols, acetaldehyde, organic acids, namely, monocarboxylates (DL-lactate), dicarboxylates (succinate), and tricarboxylates (citrate), sugar acids (D-gluconate), and various nitrogen sources comprising nitrate, ammonium hydroxide, as well as amino acids [8][9][10][12][37]. A set of metabolic advantages, as the high metabolic flux in TCA cycle, the great amino acid synthesis ability, and strong protein secretion turns C. jadinii a yet underexplored host for bioprocesses. An incomplete understanding of genetics, metabolism, and cellular physiology combined with a lack of advanced molecular tools for genome edition and metabolic engineering manipulation of C. jadinii hampered its development for cell factory utilization.

Figure 2. C. jadinii DSM 2361 morphological traits. (A) Microscopic photographs of C. jadinii cells after 3 days (A) and 12 days (B) of growth at 30 °C on yeast extract-peptone-dextrose media. Scale bars are 5.0 µm. Macro-morphological features of C. jadinii after 3 days of growth in YPD (C) and Malt Extract Agar (D) media, at 30 °C.
