

# Germ Cell Tumors for Male

Subjects: **Oncology**

Contributor: Mariana Pinto

Cancer is a leading cause of death by disease in children and the second most prevalent of all causes in adults. Testicular germ cell tumors (TGCTs) make up 0.5% of pediatric malignancies, 14% of adolescent malignancies, and are the most common of malignancies in young adult men. Although the biology and clinical presentation of adult TGCTs share a significant overlap with those of the pediatric group, molecular evidence suggests that TGCTs in young children likely represent a distinct group compared to older adolescents and adults. The rarity of this cancer among pediatric ages is consistent with our current understanding, and few studies have analyzed and compared the molecular basis in childhood and adult cancers.

## 1. Introduction

Testicular germ cell tumors (TGCTs) are a distinctive set of diseases in oncology practice due to their curability or the mixture of histologies that appears to reflect embryogenesis. TGCTs are the most common solid tumor in young adults, representing 0.4% of new cases from all sites [1]. In early ages, germ cell tumors represent 3.5% of childhood cancers, occurring in a bimodal distribution with one peak in the first four years of life and a second in adolescence [2][3], and TGCTs represents about 20% of all cases [4]. The incidence rate of testicular germ cell tumors starts to increase in the late teens (10 years old) and reaches its peak in the young adult age group [5][6][7].

TGCTs are classified according to genotype, phenotype, origin cell, and germ cell neoplasia in situ (GCNIS) relationship into three groups. Type I is rare in postpubertal testis and presents as a yolk sac tumor in children less than 6 years old and no precursor cell is identified. Type II is common in postpubertal men in the third and fourth decades of life, with GCNIS as a precursor, which leads to several histologies (see below). Type III usually affects men older than 50 years, and the spermatocytic tumor is a phenotype that is not related to GCNIS. In the current study, we focus on TGCT Types I and II [8].

TGCTs are organized into two main histological groups, known as seminoma (SE) and non-seminoma germ cell tumors (NSGCTs). Seminoma GCTs are made up of undifferentiated germ cells that can histologically resemble sperm and young oogonia, or even germ cells from developmental strains. NSGCTs are subdivided into several histologies, such as embryonal carcinoma, yolk sac tumors (YSTs), teratoma, choriocarcinoma, and mixed NSGCT, in which different histologies are present in different proportions. In contrast to embryonal carcinoma, which histologically resembles the blastocyst, YST has a complex endodermal morphology with embryonic and extraembryonic endodermal components. Mature teratomas are benign tumors, and are the most differentiated,

although they may harbor unique neural differentiation as immature teratomas. Finally, choriocarcinoma has trophoblastic differentiation and characteristically features a high level of human chorionic gonadotropin (hCG) in the bloodstream [9].

The clinical presentation of TGCTs usually involves painless swelling of one testis, and is sometimes perceived at a late stage in adults by the partners, and by parents in children. However, it may present with an enlarged tumor or even a palpable abdominal mass when the diagnosis is made at a late stage [10].

Cisplatin is the most important drug used to treat TGCTs and, in recent decades, has changed the natural history of the disease [11][12]. To date, no other drug has outperformed the results of platinum-based combinations; this includes carboplatin, which, in the adult population, has had inferior results [13][14]. Different combinations and doses have been used in protocols for adults and children, often to reduce the acute and late toxic effects, without compromising the outcomes in the latter group [15].

TGCTs have different survival rates according to the age group, with adolescents having a lower rate of event-free survival in a 3 year period (59.9%) compared to children (87.2%) or adults (80.0%) [3][16]. Twenty to forty percent of patients with metastatic testicular germ cell tumors relapse after first-line chemotherapy [11][12]. Furthermore, approximately 50% of these patients can still be cured, and histology, primary tumor location, response to first-line therapy, tumor marker concentrations, and location of metastases (liver, brain, and bone) have been proven to be important prognostic indicator factors in testicular germ cell tumors, in addition to the dose of chemotherapy [17].

Different cytogenetic abnormalities are described when comparing the age of presentation [8]. TGCTs are tumors with a low mutational load, but in their postpubertal presentation, mutations in genes such as *KRAS*, *KIT*, and *TP53* play a role, in addition to the changes in the number of copies of the *KRAS* gene [8][18]. Epigenetics has been the focus of attention in TGCTs. SE and NSGCTs have different methylation patterns, and interest in the role of miRNA is growing, particularly miR-371a-3p and miR-375 as potential biomarkers [18][19][20].

## 2. Etiopathogenesis of TGCT in Child and Adults

Curiously, the pathogenesis of TGCT begins in utero during embryogenesis, when embryonic stem cells give rise to the primordial germ cells in the genital crest present in the midline of the embryo [21][22]. Pathogenesis differs in some aspects of differentiation, histogenesis, and genomic instability between adults and children. Primordial germ cells are the most implicated in studies on the tumorigenesis of germ cell tumors, and due to their totipotent nature, TGCTs have a wide range of possible histologies. In Type I TGCTs, prepubertal teratomas, as benign tumors, have limited developmental potential and may arise during the migration of primordial germ cells. However, the chromosomal loss of 1p, 4, and 6q, in addition to 1q, 12, 20q, and 22, are implicated in the development of malignant YSTs, the histology most frequently found in testicular tumors in childhood [9][23].

## 3. Molecular Biology

Because TGCTs are a heterogeneous tumor, it is a challenge to study their genetic basis. However, in recent years, efforts have been made to understand the underlying molecular biology ([Table 1](#)) to further improve patient outcomes, particularly for those with chemoresistance and poor risk of disease.

**Table 1.** Epigenetic-based biomarkers in testicular germ cell tumors in adult and pediatric patients.

Adult		Pediatric	
Biomarker	Major Findings	Biomarker	Major Findings
<b>DNA Methylation</b>			
VGF, MGMT, ADAMTS1, CALCA, HOXA9, CDKN2B, CDO1, and NANOG	Hypermethylation of <i>MGMT</i> and <i>CALCA</i> promoters associates with non-seminoma and poor prognosis. <i>CALCA</i> associates with refractory disease. <a href="#">[24]</a>	RUNX3	<i>RUNX3</i> promoter hypermethylation was detected in YST in infants (80%). <a href="#">[25]</a>
<i>MGMT</i> , <i>RASSF1A</i> , <i>BRCA1</i> , and a transcriptional repressor gene <i>HIC1</i>	Non-seminoma showed methylation in <i>MGMT</i> , <i>RASSF1A</i> , and <i>BRCA1</i> and <i>HIC1</i> . Seminoma showed a near-absence of methylation. <a href="#">[26]</a>	APC	APC promoter hypermethylation was detected in YST in infants (70%). <a href="#">[27]</a>
<i>RASSF1A</i> , <i>HIC1</i> , <i>MGMT</i> , and <i>RARB</i>	Hypermethylation of <i>RASSF1A</i> and <i>HIC1</i> was associated with tumors resistant to cisplatin-based regimens, whereas <i>MGMT</i> and <i>RARB</i> were sensitive. <a href="#">[28]</a>	Epigenome-wide study	DMRs were identified in a set of 154 pediatric tumors from gonadal, extragonadal and intracranial locations. <a href="#">[29]</a>
<i>XIST</i>	Unmethylated DNA <i>XIST</i> fragments in seminoma and non-seminoma. <a href="#">[30]</a>		
<i>CRIPTO</i>	Hypomethylation in undifferentiated fetal germ cells, embryonal carcinoma and seminomas. Hypermethylation in differentiated fetal germ cells and the differentiated types of non-seminomas. <a href="#">[31]</a>		
<i>LINE-1</i>	Strong correlation in <i>LINE-1</i> methylation levels among affected father-affected son pairs. <i>LINE-1</i> hypomethylation was associated with the risk of testicular cancer. <a href="#">[32]</a>		
<b>Genetic</b>

## 3.4. In Vitro and In Vivo Models

Moares de Células Germinativas da Infância e

Adolescência; Lemar: São Paulo, Brazil, 2018.

In recent years, major technological advancements have led to a better understanding of the molecular mechanisms of TGCTs. However, this progress has had a slight impact on the cancer therapeutic approach, probably due to the limitation of experimental models to predict efficacy in clinical trials. In an effort to offset this

Kusler, K.; Shibusawa, A.; Matsuda, T.; Hori, T.; Nakata, K.; Kishida, Y.; Ogawa, C.; Munakata, W.; Kawai, A.; Nishimoto, H. Childhood, adolescent and young adult cancer incidence in Japan in 2009–2011. *Jpn. J. Clin. Oncol.* 2017, 47, 762–771.

It remains a challenge for the clinician to investigate the molecular and genetic mechanisms involved in the development of cisplatin resistance in TGCTs, for which the frequency of recurrence is low and the availability of histological samples post-chemotherapy is scarce, because surgical resection of the tumor is the first line of treatment [59].

In general, cisplatin resistance in TGCTs is commonly studied in primary tumors of patients who may develop metastatic disease, not in the rising incidence of testicular cancer among young men in Canada, data from 1971–2015. *Cancer Epidemiol.* 2019, 58, 175–177.

Other strategies to investigate the mechanisms associated with the resistance acquired by tumor cells to cisplatin include the use of preclinical models, in vitro and in vivo, obtained from the cultivation and exposure of TGCT cell lines to incremental doses of the drug, for long periods of time [61], in addition to the use of animal models that

Opie, J.; Fletcher, A.; Amatruda, J. *Pediatric Germ Cell Tumors: A Developmental Perspective*; Advances in the 2018–2019; 9059382.

extensively used models, which are characterized by the absence of heterogeneity and lack of microenvironment components [63]. Therefore, it is crucial to develop more accurate and clinically relevant mice models that genuinely represent TGCTs in adult and pediatric patients, according to their etiopathogenesis, histopathology, and metastatic progression, and the response of therapy. In this context, patient-derived xenograft (PDX) models have been used as an outstanding alternative [64]–[65]. PDX model development is

Different models of chemoresistant TGCT cell lines have already been developed and studied for genotypic and phenotypic changes [59]. NTERA-2 and NCCIT cisplatin-resistant cell lines were injected into immunodeficient mice and disulfiram was used to examine chemosensitization of resistant cell lines. Disulfiram in combination with alternating cisplatin/cyclophosphamide/doxorubicin and vinblastine/bleomycin regimens of
